Requirements

Core Body Temperature Estimation to Detect Ebola Virus Disease

CS 461, Fall 2017, Group 34

Claude Maimon, Brian Lee Huang , and Bianca Beauchamp

October 27, 2017

Abstract

The end goal of this project is to end up with a research paper. The paper should outline the problem that the project is trying to solve, the steps taken to solve the problem and how successfully we were at solving the problem. The paper should also allow the project to be continued if a higher percent accuracy is required. The whole process should be explained in detail allowing whoever wants to continue the project to continue without any problem. The end goal of this paper is if this project worked or not.

1 Requirements

1. The program that we are creating should be able to process data from a thermal camera. It should be able to process the image and focus on the person's upper body and record the temperature from that area.

2. The program should be able to compare the temperature to the public average and check whether or not a person is above the average.

3. The whole process of taking the image and analyzing it should be faster than a regular check up.

4. The program should be easy to use. Zero background knowledge should be required to operate it.

5. The code will be able to cut out the person from the background.

6. We should provide multiple different statistical analysis of the data and provide the analysis with the smallest error.

7. We should be able to isolate the person in the image, and then isolate the persons head in the image.

8. A graph should be generated from a single person's data.

9. Ear temperature of the person should also be taken. We will then use this temperature to compare it to what our model predicted.

10. A mathematical model should be created out of all the data that is collected. The model will then be used to predict a person's core temperature.

2 Stretch Goals

1. We will go out and collect data to feed into the model, and make it able to predict more accurately.
